THE IMPACT OF REMITTANCES ON HOUSEHOLD SAVINGS IN THE BALTICS

Abstract

Proper understanding and monitoring of household savings are crucial to effective macroeconomic policies targeted at balanced and sustainable economic growth. Remittances, as a financial flow of foreign capital, can create a vital part of private savings. This paper is aimed at identifying whether remittances contribute to household savings in the Baltics along with other macroeconomic variables in a post-crisis period, during which the relative smoothing and convergence of economic development of the Baltic countries after the sharp financial distress in 2009 can be observed. The following methods of panel data regression analysis were employed: fixed effects and OLS. The results of the econometric analysis based on both fixed effects and OLS methods reveal that remittances are an essential driver of savings in the Baltics in the long run. Savings in the Baltics are not significantly influenced in the short term by sharp economic fluctuations, but are dependent on demographic factors and foreign capital, which can bring instability in economic development and financial flows of the region.

INTRODUCTION

Remittances account for a significant part of foreign capital flows in developing countries. Remittances are considered to have a positive effect on the economy and be beneficial for development (e.g. Aguinias, 2006, Ghosh, 2006). However, it is not clear enough how remittances affect different aspects of wealth of a recipient economy. The study of the Asian Development Bank and the World Bank (2018) has documented that remittances are acyclical regarding the recipient state. Remittances appear to be less volatile than other types of financial flows, including both foreign direct investment (FDI), and official development assistance (ODA) and export (Gavurova et al., 2020). However, they are more procyclical than ODA and less procyclical than financial flows. Remittances demonstrate flexibility during sudden financial crises and breaks and remain steady, whereas total financial flows drop abruptly during such episodes, thus, offsetting the effects of volatile financial flows. Households that receive international remittances spend more on health, education and housing than those that do not. Remittances also contribute to smoothing out consumptions of receiving households and facilitating them to mitigate sudden economic disaster better.

The main issue of remittances regarding development is that the majority of remittances are spent on consumption, and minimal share is invested (Basu & Rajan, 2018). It should be noted that recently the spending on education and health of remittance-receiving households is considered as investment in human capital as in the long run they contribute to the capacity development of labor force in the country.

Remittance-receiving households tend to raise their spending on education and health if they obtain more significant amounts of remittances. From this point of view, remittances are spent not only for consumption, but also contribute to the labor productivity (Akter, 2018; Matuzeviciute & Butkus, 2016) and the total factor productivity of the country (Kumar & Stauvermann, 2014; Kumar et al., 2018). According to studies, remittances often appear to be more beneficial for local economies than FDI and ODA (Makhlouf, 2019).

When investments considered as financial investments, such as securities or savings, benefit from remittances at a macro level, investing them in public goods such as physical infrastructure is the better path. In turn, low savings rate, in particular, household savings can create concern for policymakers due to the following reasons. First, the household sector is a primary sector of the national economy that contributes to savings. Second, household savings may finance domestic and foreign investment, contributing to economic growth and development. Third, goods in the form of savings can shift efficiently from generation to generation. Fourth, saving behavior of households is also crucial for monetary authorities and financial institutions. The overall amount of household savings influences not only the final consumption of households, hence demand of the retail loans, but also banks funding model, interest rates, exchange rates, current account balance and the resilience of the economy to shocks. Therefore, proper understanding and monitoring of the household savings are crucial to developing and implementing efficient macroeconomic policies targeted at balanced and sustainable economic growth. A low household savings rate can indicate fewer job creations, and therefore a lower quality of life. Remittances, as a financial flow of foreign capital, can create a vital part of private savings.

This paper is aimed at identifying whether remittances contribute to household savings in the Baltics along with other macroeconomic variables in a post-crisis period, during within which the relative smoothing and convergence of economic development of the Baltic countries can be observed after sharp economic distress in 2009.

1. LITERATURE REVIEW

1.1. The effect of remittances on household savings

The empirical literature in most cases indicates a positive association between household savings and remittances across countries (Ashraf et al., 2014; Esteves & Khoudour-Casteras, 2011; Iheke & Aniocha, 2017). In particular, Gani (2016) has found a positive connection between remittances and private savings in selected Asian countries. Haider et al. (2016) have explored the effect of remittance on consumption and the savings behavior of rural households in Bangladesh and found out a substantial impact of remittances on consumption and savings. Baldé (2011) concluded about a significant positive impact on savings in Sub-Saharan Africa during 1980–2004. Quartey et al. (2019) have investigated the linkages between remittances and households savings in Ghana and concluded that households receiving international remittances have a higher probability of savings

comparing to households that obtain only domestic remittances. Raza (2015) explored the influence of FDI and workers' remittances on the private savings of Pakistan and concluded about FDI and workers' remittances having a considerable positive impact on private savings in both short and long perspectives. Causality analyses have confirmed the bidirectional causal relationship between FDI and remittances with private savings.

Some studies highlight the negative influence of remittances on savings due to the indicated positive influence on consumption. In particular, Devasagayam et al. (2016) have argued about the negative impact of remittances on domestic savings by researching their connection in the Middle East and North Africa (MENA) countries between 1977 and 2014. They concluded about the positive impact of remittances on the economic growth through stimulating household consumption that increases the expected consumption and may increase imports, which cuts savings owing to low levels of income. For the same region, Sabra (2016)

has studied the impact that remittances have on investment, household savings and economic growth. It was found out that remittances had a positive influence on growth through stimulating family consumption that may rise imports, which cuts savings under the low levels of income.

1.2. Remittances in the Baltics

There is vast literature that explores the impact of remittances on economic growth indicating their relatively positive influence on the economy of receiving countries and the development of the countries of different income levels (Arif et al., 2019; Carment & Calleja, 2018; Chezum et al., 2018; Grabowska et al., 2017; Maduekwe & Adesina, 2017; Meseguer et al., 2017; Pajaron, 2017; Wadood & Hossain, 2017; Dvorský et al., 2019). However, they pay little attention to their influence on household savings and, in particular, in the Baltics region. The Baltics region, along with Romania and Bulgaria, represents a region with lower household saving rates when compared to other EU region countries, whereas the remittances are higher than in other more developed member states. After EU enlargement in 2004, the remittances in the Baltics have increased considerably. However, after the crisis of 2008, they remained stable, ranging from 1.72 to 2.25% of GDP. On the other hand, savings in EU15 countries are considerably higher (13-15% of disposable income) and remittances are significantly lower (less than 1% of GDP) (World Bank, retrieved on October 29, 2019).

According to Strielkowski et al. (2018), international migration and remittances have a considerable positive impact on the economic development of the Baltic states in comparison with other macroeconomic factors. An OECD study on emigration in the Baltics highlights the significance of remittances for households, particularly during the world financial crisis of 2008, as remittances mitigated the consequences of the crisis, as well as compensated for financial distress, especially in Lithuania (OECD, 2013). Azam (2016) has studied the impact of remittances on poverty alleviation in a global perspective, including Baltic countries, and found out there are substantial possible benefits related to foreign remittances for poor people. The regional research of Zuniga (2011) has shown that remittances play a vital role in the economy of countries, including the Baltics. Independent of

the role of institutions, remittances positively influence economic growth; however, they are used for consumption rather than savings. The results of Kumar and Stauvermann (2014) have demonstrated that in Lithuania, the remittances have a dynamic short-run and a significant long-run effect on the output per worker. Moreover, the causality analysis has shown a mutually underpinning effect between the output per worker and capital per worker, as well as unidirectional causality from remittances to output per worker.

Thus, remittances have an undoubted effect on the economy. However, there is no consensus about the nature of their influence on the savings rate, hence giving grounds for further research.

1.3. Factors affecting household saving behavior

1.3.1. Economic factors

Unemployment rate and inflation are the most widely used indicators for assessing the influence of uncertainty on household savings. When anticipating economic distress, households tend to save more as a mitigating measure. An increase in the unemployment rate and inflation increases the volume of household savings (Kostakis, 2013; Syed et al., 2017; Temel Nalın, 2013a). Temel Nalın (2013b) investigated the drivers of household saving and portfolio choice behavior in Turkey using the inflation index and concluded that inflation increased the probability of household saving. Niculescu-Aron and Mihăescu (2012) employed first-order differences in the inflation rate in two panels of the states – Western Europe and Central and Eastern Europe. They found out in both panels that a rise in inflation was positively associated with household savings.

Fiscal policies may have a considerable effect on household savings. Active fiscal policies aimed at stimulating consumption can adversely affect the savings. To stimulate the economy, the government can increase government expenditure and run a budget deficit, which may decrease present household consumption expenditure if households anticipate future tax rises to support public debt (OECD, 2018). An assumed consumption smoothening, a drop in the expected future in-

come will decrease current consumption and rise current household savings. The fiscal policy of the states is assessed by the rate of the government surplus in % of GDP, rate of public debt in % of GDP, social protection expenditures by the government in % of GDP and the portion of indirect taxation in total taxation.

The net inflow of FDI is negatively associated with household saving. Hence, FDI seems to be a substitute for domestic saving (Rocher et al., 2015).

1.3.2. Demographic factors

The concept of consumption smoothing over a lifetime suggests that young people tend to save less than adults. Elderly individuals are likely to dissave. Thus, countries with high age dependency are likely to have lower household savings (Edwards, 1995; Loayza et al., 2000).

An increasing life expectancy may also affect households savings. Demographic projections show that the population is rapidly ageing in many of the EU member states. Therefore, households may rise their savings as they face a longer retirement. Thus, life longevity can also be a potential driver to capture this effect (Bloom et al., 2002; Carvalho et al., 2017). Often, older people live alone, which drops their disposable income. Therefore, assuming that women are over-represented among the older age group of the population, their saving rates may be negatively related to life expectancy (OECD, 2017).

1.3.3. The effect of financial literacy on household saving behavior

Financial literacy is another critical factor that influences households saving behavior. Shortage of primary financial education may be related to the lack of sufficient retirement planning and lack of wealth accumulation (Reisch & Zhao, 2017). It may as well cause the loss of the link between households and financial institutions, hence causing information asymmetry. There is also a positive association between household savings and financial literacy, wealth accumulation and retirement planning (Ameriks et al., 2002; Hastings et al., 2013; Lusardi & Mitchell, 2011; Lusardi, 2004; Stango & Zinman, 2009; van Rooij

et al., 2011). Jappelli and Padula (2013) have identified that individuals benefit from investment in financial literacy as financial literacy contributes to an increase in wealth returns. Batsaikhan and Demertzis (2018) have indicated that in the developed countries, there is a positive association between savings, the borrowing balance of the country and the level of financial literacy. In Denmark and Sweden, which are the countries with the highest financial literacy rates, almost all respondents reported doing savings at a financial institution in the last 12 months. The authors have also indicated that the financial literacy rank has a positive linkage to both saving borrowing and behaviors, representing that in countries with higher literacy rates, adults have a higher active link with financial institutions.

2. METHODOLOGY

2.1. Model specification

Based on the theoretical grounds and empirical findings, a regression model was used to assess the impact of remittances on household saving behavior in the Baltics along with other macroeconomic determinants (Table 1) annually in the post-crisis period from 2010 to 2017. For the regression analysis panel data was employed with the use of the following methods: fixed effects and OLS.

The model equation is as follows:

$$\begin{aligned} \text{Savings} = & \alpha_0 + \alpha_1 l_ \text{Remittances} + \\ & + \alpha_2 l_ \text{Life_expect} + \alpha_3 \text{Unempl_perc} + \\ & + \alpha_4 \text{Old_age_depend} + \\ & + \alpha_5 \text{Inflation_HICP} + \\ & + \alpha_6 \text{FDI_Inflow} + \alpha_7 \text{Gov_debt} + \\ & + \alpha_8 \text{NS_fin_edu} + U_i. \end{aligned}$$

2.2. Data: Common economic features of the Baltics

Latvia, Lithuania and Estonia share a similar history and development aspects. The countries took back their independence from the Soviet Union in the early 1990s before EU accession in 2004. The Baltic countries show key similarities regard-

Table 1. Description of variables

Variable	Description	Unit of measure	Source	The expected sign of the influence on savings
Savings: dependent variable	The gross saving rate of households	% of gross disposable income	(Eurostat)	
I_Remittances	Remittances in receiving countries	Millions of US dollars	(World Bank)	+
I_Life_expect	Life expectancy at the age of 65	years	(Eurostat)	+
Unempl_perc	The unemployment rate	% of the active population	(Eurostat)	+
Old_age_depend	Old dependency ratio: population 65 and over to population 15 to 64 years	ratio	(Eurostat)	–
Inflation_HICP	Harmonised Indices of Consumer Prices, annual average rate of change	%	(Eurostat)	+
FDI_inflow	Foreign direct investment, net inflows	% of GDP	(World Bank)	–
Gov_debt	General government gross debt	% of GDP	(European Commission)	–

ing their economic structure, geography and demography. Among their noticeable similarities are the characterized economic cycles (Figure 1), economic policies, monetary and banking sectors and population dynamics (Figure 2) (Poissonnier, European Commission, & Directorate-General for Economic and Financial Affairs, 2017).

The transition to a market economy after recapturing independence shadowed a similar pattern in the Baltics. All three countries followed a common goal to join the EU and the monetary union. Estonia, Latvia and Lithuania have comparatively small government sectors and liberal economic policies. Foreign investors, in no small extent,

consider the Baltics as a single market with a single local headquarter and sales policy.

Regarding monetary policy, it should be noted that monetary authorities of all three countries strive for a steady exchange rate of their currencies. The Latvian Lats was primarily pegged to the IMF special drawing rights. The Estonian Kroon was pegged to the Deutsche Mark since its introduction in 1992. The Lithuanian Lita was pegged to the US Dollar from 1994. Later all Baltic currencies pegged to the Euro and joined the European exchange rate mechanism (ERMII) in 2004 and 2005 before joining the Euro Area between 2011 and 2015.

Source: Eurostat.

**Figure 1.** GDP growth rate: volume percentage change on the previous year in the Baltics and EU28, %

Figure 2. Population dynamics in the Baltics and EU28, thousands

According to statistics, the Baltic countries also demonstrate similar household savings dynamics (Figure 3).

It should be noted that households saving rates need to be interpreted carefully due to data soundness and limited international comparability. Saving rates seem to be in divergence with other economic variables. In particular, household saving rates have been negative over the last twenty years in Romania and Bulgaria, as shown in Figure 3. It means that households in these EU member states spend considerably and interminably more than they earn. However, economic reality does

not provide evidence to this, since households debt-to-income ratios stay relatively low in these states and have even been declining since 2009.

Given the typical path of economic development and saving dynamics, the Baltics represent a stable research panel. The next section studies the influence of remittances on household savings in the Baltics.

3. RESULTS AND DISCUSSION

The regression analysis has been conducted by employing panel data with the use of fixed effects and

Figure 3. The household saving rate in the Baltics, % of disposable income

OLS methods. Summary statistics are represented in Table 2. Regression analysis results are shown in Table 3. The collinearity test is presented in Table 4, and tests for differing group intercepts, heteroscedasticity and error distribution are shown in Table 5.

Table 5. Test for differing group intercepts, heteroscedasticity test, error distribution test

Tests/Models	Model 1	Model 2	Model 3
	Baseline model	Baseline model	Modified model
	Fixed effects	OLS	OLS
Test for differing group intercepts	10.677 (0.001)		
Wald test for heteroskedasticity	2.159 (0.54)		
White's test for heteroskedasticity		21.733 (0.114)	20.329 (0.087)
Test statistic for normality of residual test	0.186 (0.91)	0.799 (0.67)	0.874 (0.645)

Model 1 (Table 3) represents the results of fixed effects estimation; Model 2 shows the results of OLS estimation, Model 3 represents the results of OLS estimation with the use of modified baseline model due to detected collinearity problem (Table 4). The variable “life expectancy” has been removed from Model 3. A test for differing group intercepts has defined that fixed effects are a proper estimation method in terms of an employed regression model. Both the Wald test for heteroscedasticity in the case of fixed effects estimation and White's test for heteroscedasticity in the case of OLS estimation have shown that heteroscedasticity is not present. A test statistic for normality of residual test has identified an error that is normally distributed in all estimations.

Both fixed effects and the OLS method have shown that remittances have a strong positive influence on household savings in the Baltics in the post-crisis period from 2010 to 2017.

According to fixed effects, life expectancy was negatively associated with household savings in

the Baltics, which does not support the expectations. It can be explained by the fact that people anticipate that an increase in life expectancy will be accompanied by an increase in the retirement age or potential pension benefit in the case of delaying the earliest possible retirement time. Hence, they could rely more on their longer work career than on savings. This assumption may also be supported by the fact that the government in most of the EU member states allow the people to work when receiving an old-age pension (Europäische Kommission & Europäische Kommission, 2018).

The received positive link between old-age dependency and household savings also does not support our assumptions according to which it should be negative. The result received can indicate that population ageing may not result in lower saving rates in the future if the retirement age rises. It can be explained by the fact that the ageing population could wish to support their grand-

children or working-aged children. Hence, public pensions can appear as a transfer that supports the household.

Fixed effects estimation demonstrated that the uncertainty indicators – unemployment and inflation – were not significant determinants of household savings in the Baltics. However, an OLS estimation has revealed a positive association between unemployment and savings, which confirms the assumption. Government debt has appeared to be an insignificant regressor in the fixed-effects estimation. However, OLS estimation has revealed a negative link between this variable and household savings, which supports the assumption.

The FDI inflow in fixed effects estimation appeared to be negatively linked to savings, which is following the assumptions. However, in the OLS estimation, this variable was not significant.

CONCLUSION

This paper identified the influence of remittances on household savings in the Baltics, along with other macroeconomic variables in the post-crisis period. The relative smoothing and convergence of economic development of the Baltic countries can be observed after the sharp economic distress in 2009. The significance of remittances for household savings in the Baltics was studied along with other macroeconomic variables: unemployment rate, inflation, FDI inflows, and government debt and demographic variables: life expectancy, old-age dependency, and the introduction of the National Strategy of financial education as a proxy for financial literacy.

Fixed effects and OLS methods were employed for the regression analysis. Both estimations have revealed that remittances are an essential driver of savings in the Baltics. The estimation with fixed effects association between demographic indicators did not support the hypothesis advanced in this paper. However, the issue lies in the complexity of savings due to high subjectivity.

According to the fixed effects estimation, uncertainty indicators – inflation and unemployment – appeared to be insignificant factors of saving. Among other employed factors, only FDIs are significant. However, OLS estimation results have shown that government debt and unemployment do influence savings.

The fixed effects results indicate that in general savings in the Baltics are not significantly influenced in the short term by sharp economic fluctuations, but are dependent on demographic factors and foreign capital, which can bring instability in economic development and financial flows of the region. Thus, in the light of this, remittances, given their nature described above, are a vital source of savings in the long run.
